$\qquad$
$\qquad$
$\qquad$

An astronaut who weighs 150 lb on earth, travels away from earth in a rocket ship. As she gets further away from earth, the pull of gravity decreases and her weight goes down as follows:

| Weight | $\underline{\text { Miles }}$ <br> from |
| :---: | :---: |
| 150 lb | $\frac{\underline{\text { Earth }}}{0}$ |
| 80 lb | 1400 |
| 40 lb | 3500 |
| 20 lb | 5500 |
| 15 lb | 7000 |
| 12 lb | 9000 |
| 10 lb | 10000 |
| 7 lb | 13000 |
| 6 lb | 14000 |

Prepare a graph showing the relationship between weight and distance from earth.

## PROCEDURE

1. On a separate sheet of graph paper, set up a graph using appropriate axes, intervals, and origin. Let Weight be on the $X$-axis, and Miles from Earth be on the $Y$-axis. Plot the points.
2. After plotting the points, draw the best straight line or curve.
3. Read the values from your graph to answer the questions below.

CONCLUSIONS

1. How high above the earth is the astronaut when she weighs 100 lb ? $\qquad$
2. How much does the astronaut weigh 1,000 miles from earth? $\qquad$
3. What type of relationship exists between weight and distance from earth? $\qquad$
